Постановка задачи

Вариант 5.

Составить программу на языке Си, обрабатывающую данные в многопоточном режиме. При обработке использовать стандартные средства создания потоков операционной системы (Windows/Unix). Ограничение максимального количества потоков, работающих в один момент времени, должно быть задано ключом запуска вашей программы. Так же необходимо уметь продемонстрировать количество потоков, используемое вашей программой с помощью стандартных средств операционной системы. В отчете привести исследование зависимости ускорения и эффективности алгоритма от входных данных и количества потоков. Получившиеся результаты необходимо объяснить.

Отсортировать массив целых чисел при помощи чётной-нечётной сортировки Бетчера.

Общий метод и алгоритм решения

Использованные системные вызовы:

- write; – записывает данные в файл.
- read - читает данные из файла
- pthread_create - создаёт поток
- pthread_join - ожидание множества потоков
- pthread_mutex_init - создание мьютекса
- pthread_mutex_destroy - уничтожение мьютекса
- pthread_mutex_lock - блокировка мьютекса
- pthread_mutex_unlock - разблокировка мьютекса
- gettimeofday - получение текущего времени (для бенчмарка)

В лабораторной работе я использовал собственную реализацию вывода строки в stdout (iolib/std_out)? которая использует системный вызов write.

В задании требуется реализовать чётную-нечётную сортировку Бетчера. Идея данный алгоритм схож с сортировкой слиянием, но в отличие от неё использует чётно-нечётные перестановки. Идея алгоритма в том, что мы последовательно рассматриваем подмассивы разных размеров, как и в сортировке слиянием, мы будем их сливать (при помощи операции compare and exchange), но в отличии от сортировки слиянием, здесь мы используем итеративный подход вместо рекурсии и вместо разбиения массива посередине, мы разбиваем массив на чётную половину и нечётную. Сам алгоритм можно описать при помощи псевдокода следующим образом:

```
for p = 1, 2, 4, 8, ... # пока p < n for k = p, p/2, p/4,
p/8, ... # пока >= 1 for j = mod(k,p) to (n-1-k) с
шагом 2k for i = 0 to min(k-1, n-j-k-1) с
единичным шагом if floor((i+j) / (p*2)) ==
floor((i+j+k) / (p*2)) compare and sort elements (i+j)
and (i+j+k)
```

Для того чтобы распараллелить данный алгоритм, вынесем цикл с переменной j в отдельную функцию, плюс будем вычислять отступ с учётом кол-ва потоков и номером текущего потока, таким образом. Для того, чтобы избежать race condition при обращении к исходному вектору, будем использовать мьютекс. Будем использовать вызов `pthread_join` для ожидания списка потоков.

Код программы

main.cpp

```
##include <vector>
#include <pthread.h>
#include <mutex>
#include <sys/time.h>
#include "iolib/std.h"

pthread_mutex_t mutex;

struct ThreadData
{ std::vector<int> *sequence; int
  n; int p; int k; int

Вывод

Задание мне показалось интересным, так как многопоточное программирование - одна из самых частых и важных тем. Я столкнулся с многими проблемами, самой сложной задачей, мне показалось распараллеливание исходного алгоритма

Число потоков	Время исполнения (с)	Ускорение	Эффективность
1	1.006487	1	1
2	0.582498	1.72	0.86
4	0.332793	3.02	0.98
8	0.267251	3.76	0.47
16	0.225936	4.45	0.27
